# Doubly Robust Estimates for Binary Longitudinal Data Analysis with Missing Response and Missing Covariates 

#### Abstract

Longitudinal studies often feature incomplete response and covariate data. Likelihood based method such as EM algorithm gives consistent estimates for data are missing at random provided that the response model and the missing covariate model are correctly specified; while we can misspecify (or do not even to estimate) the distribution of the missing indicators. An alternative method is the weighted estimating equation which gives consistent estimates if the missing data models and response models are correctly specified; but we can misspecify (or do not even to estimate) the distribution of the missing covariates. In this paper we develop a doubly robust estimate method for longitudinal data with missing response and missing covariate when data are missing at random. This method is appealing in that it can provide consistent estimates if either the missing data model or the missing covariate model is correctly specified. Simulation studies demonstrate that this method performs well in a variety of situations.

KEYWORDS: Doubly robust; estimating equation; missing at random; missing covariate; missing response.

## 1 Introduction

Incomplete longitudinal data often arise in comparative studies because of difficulties in ascertaining responses at scheduled assessment times, partially completed forms or questionnaires, patients refusal to undergo complete examinations, or study subjects failing to attend a scheduled clinic visit. Problems ensue if the mechanism leading to the missing data is dependent on the response or covariates. Analyses based only on individuals with complete data can lead to invalid inferences in this case. Under a missing completely at random (MCAR) mechanism (Little \& Rubin, 2002), analyses based on generalized estimating equations (GEE) (Liang \& Zeger, 1986) yield consistent estimates of the regression parameters. However, when the data are missing at random (MAR) or missing not at random (MNAR) (Little \& Rubin, 2002), analyses based on GEE give inconsistent estimates. Robins et al. (1995) developed a class of inverse probability weighted generalized estimating equations (IPWGEE) which can yield consistent estimates when data are MAR. The weights are obtained from models for the missing data process, and these models must be correctly specified for the resulting estimators to be consistent. Alternatively, one can use maximum likelihood method to estimate the parameters, and it gives consistent estimate if the model is correctly specified.

The literature on methods for missing data has primarily addressed either missing response or missing covariate data (see, e.g., Fitzmaurice et al., 2001; Horton \& Laird, 1998; Ibrahim et al., 2001; Lipsitz et al., 1999; Zhao et al., 1996), but relatively little work has been done when both can be missing. In practice, of course, data are often unavailable for both responses and covariates. Chen et al. (2008) provide a careful investigation of likelihood methods for missing response and covariate data via the EM algorithm. Shardell \& Miller (2008) propose a marginal modeling approach to estimate the association between a time-dependent covariate and an outcome in longitudinal studies with missing response and missing covariate, but they focus on methods with an assumption that responses are independent.

For the IPWGEE, to obtain a consistent estimate we need to correctly model the missing data process and also need to correctly model the response process given the covariates. If the missing data process model is misspecified, it can give biased estimate. While we can misspecify the distribution of the missing covariates. That means, the IPWGEE method is sensitive to the misspecification of the missing data model but robust to the misspecification of the covariate process model. For the maximum likelihood method, we do not need to specify the missing data models when missing data are MAR, but we must correctly specify the joint distribution of the response and the covariates that subject to missing. If the distribution of the covariates is misspecified, the maximum likelihood can give inconsistent estimate. That is to say, the maximum likelihood method is sensitive to the misspecification of the covariate model but robust to the misspecification of the missing data model when data are MAR.

A hybrid approach is the doubly robust estimate introduced by Lipsitz et al. (1999), in which they only considered the cross-sectional studies with a missing covariate. This is an estimating equation approach with properties similar to maximum likelihood. To obtain a consistent estimate of the regression parameters, either the missing-data model or the distribution of the missing data given the observed data must be correctly specified, which is more robust to the IPWGEE and maximum likelihood method. The literature for the doubly robust estimate includes Robins \& Rotnitzky (2001), Van der Laan \& Robins (2003), Scharfstein et al. (1999), Lunceford \& Davidian (2004), Carpenter et al. (2006), Davidian et al. (2005), Bang \& Robins (2005), and Kang \& Schafer (2007), Seaman \& Copas (2009). This literature, however, focuses primarily on monotone missing data patterns; Vansteelandt et al. (2007) developed regression models for the mean of repeated outcomes under nonignoreable nonmonotone nonresponse, where they focus on conducting inference about the marginal mean and the conditional mean given the baseline observed covariates. Little work has devoted to the longitudinal studies with both missing response and missing covariates. In this paper, we extend the method of Lipsitz et al. (1999) to accommodate binary longitudinal data with both missing response and missing covariates. This approach is appealing in that it can
not only deal with the missing response and missing covariate problem with intermittently missing data pattern but yields the optimal estimator.

The remainder of this paper is organized as follows. In Section 2, we introduce notation and models. In Section 3, we give the forms of the estimating equations and provide details on estimation and inference. Simulation studies are given in Section 4. Data arising from an Alzheimer's diease are analyzed in the application in Section 5. Concluding remarks are made in Section 6.

## 2 Notation and Models

### 2.1 Response Process

Suppose that $n$ individuals are to be observed, with $J_{i}$ repeated measurements for subject $i, i=$ $1, \ldots, n$. Let $Y_{i}=\left(Y_{i 1}, Y_{i 2}, \ldots, Y_{i J_{i}}\right)^{\prime}$ denote the $J_{i} \times 1$ binary response vector for subject $i$ that may be missing at some time points. Let $X_{i}=\left(X_{i 1}, X_{i 2}, \ldots, X_{i J_{i}}\right)^{\prime}$ be the covariate vector that may be missing and $Z_{i}=\left(Z_{i 1}^{\prime}, Z_{i 2}^{\prime}, \ldots, Z_{i J_{i}}^{\prime}\right)^{\prime}$ be the covariate matrix that are always observed, where $Z_{i j}$ is the covariate vector for subject $i$ at time $j$.

Define $\mu_{i j}=E\left(Y_{i j} \mid X_{i}, Z_{i}\right)=P\left(Y_{i j}=1 \mid X_{i}, Z_{i}\right)$, and let $\mu_{i}=\left(\mu_{i 1}, \mu_{i 2}, \ldots, \mu_{i J_{i}}\right)^{\prime}$. Provided that the mean structure of $Y_{i j}$ depends on the covariate vector for subject $i$ at time $j$ (Pepe \& Anderson, 1994; Robins et al., 1999), we may consider the models for the mean of the form

$$
g\left(\mu_{i j}\right)=X_{i j} \beta_{x}+Z_{i j}^{\prime} \beta_{z}
$$

for $j=1, \ldots, J_{i}, i=1, \ldots, n$, where $\beta=\left(\beta_{x}, \beta_{z}^{\prime}\right)^{\prime}$ is a vector of regression parameters. Here we suppose only one covariate $X_{i j}$ is potentially missing. Comments on how to deal with the problem when multiple covariates may be missing are given in the discussion. The variance for the response $Y_{i j}$ is specified as

$$
v_{i j}=\operatorname{Var}\left(Y_{i j} \mid X_{i}, Z_{i}\right)=\mu_{i j}\left(1-\mu_{i j}\right),
$$

which depends on the regression parameter vector $\beta$.

Let $Y_{i j}^{*}=\left(Y_{i j}-\mu_{i j}\right) / \sqrt{v_{i j}}, \rho_{i j k}=E\left(Y_{i j}^{*} Y_{i k}^{*}\right), \rho_{i j_{1} j_{2} \cdots j_{K}}=E\left(Y_{i j_{1}}^{*} Y_{i j_{2}}^{*} \cdots Y_{i j_{K}}^{*}\right)$ be the $K$ thorder correlation among components $Y_{i j_{1}}, Y_{i j_{2}}, \ldots, Y_{i j_{K}}$ of $Y_{i}$, and $\rho$ denote all the correlation parameters. For given subject $i$, the joint probability for a response vector $Y_{i}$ can be expressed via the Bahadur representation (Bahadur 1961), which is given by

$$
\begin{align*}
P\left(Y_{i}=\right. & \left.y_{i} \mid X_{i}, Z_{i}\right)=\prod_{j=1}^{J_{i}}\left\{\mu_{i j}^{y_{i j}}\left(1-\mu_{i j}\right)^{1-y_{i j}}\right\} \cdot\left\{1+\sum_{j<k} \rho_{i j k} y_{i j}^{*} y_{i k}^{*}\right. \\
& \left.+\sum_{j<k<l} \rho_{i j k} y_{i j}^{*} y_{i k}^{*} y_{i l}^{*}+\cdots+\rho_{i 1 \cdots J_{i}} y_{i 1}^{*} \cdots y_{i J_{i}}^{*}\right\} \tag{1}
\end{align*}
$$

where $y_{i}$ is a realization of $Y_{i}$, and $y_{i j}^{*}$ is a realization of $Y_{i j}^{*}$. This joint density requires modeling the correlation structures of all orders. In practice, it is often the case that the second order dominates the association structure while the third and higher order association is null or nearly null. Under such circumstances, then the joint density is given by

$$
\begin{equation*}
P\left(Y_{i}=y_{i} \mid X_{i}, Z_{i}\right)=\prod_{j=1}^{J_{i}}\left\{\mu_{i j}^{y_{i j}}\left(1-\mu_{i j}\right)^{1-y_{i j}}\right\} \cdot\left\{1+\sum_{j<k} \rho_{i j k} y_{i j}^{*} y_{i k}^{*}\right\} . \tag{2}
\end{equation*}
$$

In the following, we assume that the third and higher order association for $Y_{i}$ is null, and let $C_{i}(\rho)$ denote the correlation matrix of $Y_{i}$.

### 2.2 Missing Data Process

To indicate the availability of data we let $R_{i j}=0$ if $Y_{i j}$ and $X_{i j}$ are missing, $R_{i j}=1$ if $Y_{i j}$ is missing and $X_{i j}$ is observed, $R_{i j}=2$ if $Y_{i j}$ is observed and $X_{i j}$ is missing, and $R_{i j}=3$ if $Y_{i j}$ and $X_{i j}$ are observed. Let $R_{i}=\left(R_{i 1}, R_{i 2}, \ldots, R_{i J_{i}}\right)^{\prime}$, and $\bar{R}_{i j}=\left\{R_{i 1}, \ldots, R_{i, j-1}\right\}$.

Instead of modeling the joint probability $P\left(R_{i}=r_{i} \mid Y_{i}, X_{i}, Z_{i}\right)$ for $R_{i}$ directly, since we are focusing on the longitudinal setting we restrict attention to conditional models of the form $P\left(R_{i j}=\right.$ $\left.r_{i j} \mid \bar{R}_{i j}, Y_{i}, X_{i}, Z_{i}\right)$ which reflect the dynamic nature of the observation process over time; we can then obtain $P\left(R_{i}=r_{i} \mid Y_{i}, X_{i}, Z_{i}\right)$ through

$$
\prod_{j=2}^{J_{i}} P\left(R_{i j}=r_{i j} \mid \bar{R}_{i j}, Y_{i}, X_{i}, Z_{i}\right) \cdot P\left(R_{i 1}=r_{i 1} \mid Y_{i}, X_{i}, Z_{i}\right)
$$

Let $\lambda_{i j k}=P\left(R_{i j}=k \mid \bar{R}_{i j}, Y_{i}, X_{i}, Z_{i}\right)$ denote the conditional probability, $k=0,1,2,3$. We write these probabilities as conditional on the previous missing data indicators for the response and covariate, as well as the full vector of responses and covariates. The formulation thus far encompasses MCAR, MAR and MNAR mechanisms since we have written the missing data model at assessment $j$ as depending on the full vector of responses $Y_{i}$ and covariates $X_{i}$. For missing at random mechanisms we require

$$
\begin{equation*}
P\left(R_{i}=r_{i} \mid Y_{i}, X_{i}, Z_{i}\right)=P\left(R_{i}=r_{i} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right), \tag{3}
\end{equation*}
$$

where $Y_{i}^{o}$ and $X_{i}^{o}$ represent the observed components of $Y_{i}$ and $X_{i}$, respectively. However, in the longitudinal setting with our conditional formulation it is very natural to make the further assumption that

$$
\begin{equation*}
P\left(R_{i j}=r_{i j} \mid \bar{R}_{i j}, Y_{i}, X_{i}, Z_{i}\right)=P\left(R_{i j}=r_{i j} \mid \bar{R}_{i j}, Y_{i}^{o}, X_{i}^{o}, Z_{i}\right) \tag{4}
\end{equation*}
$$

for each time point $j$. It can be seen that (4) implies (3), but not vice versa. Moreover, while mechanism (3) covers a larger class of MAR models than (4), models under (4) are easier to formulate and interpret. Finally, many useful models can be embedded into the class characterized by (4), and this approach has been commonly used to model missing data processes with a MAR mechanism (e.g., Robins et al., 1995). For intermittently MAR data, it is often convenient to adopt the further assumption that the missing data indicators at time $j$ depend only on the previously observed outcomes and covariates.

To model $\lambda_{i j k}$, typically, a generalized logistic link, by using $\lambda_{i j 0}$ as a reference, may relate a linear function of $\bar{R}_{i j}, Y_{i}, X_{i}$ and $Z_{i}$, i.e.

$$
\log \left(\frac{\lambda_{i j k}}{\lambda_{i j 0}}\right)=u_{i j k}^{\prime} \alpha_{k}, \quad k=1,2,3,
$$

where $u_{i j k}$ may be a subset of $\left\{\bar{R}_{i j}, Y_{i}, X_{i}, Z_{i}\right\}$. Let $\alpha=\left(\alpha_{1}^{\prime}, \alpha_{2}^{\prime}, \alpha_{3}^{\prime}\right)^{\prime}$.
Let $\pi_{i j}=P\left(R_{i j}=3 \mid Y_{i}, X_{i}, Z_{i}\right)$ be the marginal probability of observing subject $i$ at time $j$,
given the entire vectors of responses and covariates; it is given by

$$
\pi_{i j}=\sum_{r_{i 1}, \ldots, r_{i, j-1}} P\left(R_{i j}=3, R_{i, j-1}=r_{i, j-1}, \ldots, R_{i 1}=r_{i 1} \mid Y_{i}, Z_{i}, X_{i}\right) .
$$

This marginal probability can be expressed in terms of the marginal (conditional) probabilities, $\lambda_{i j k}{ }^{\prime} s$.

### 2.3 Missing Covariate Model

Since subjects can have $X_{i}$ missing, we must consider the density of $X_{i}$ in some situations to obtain valid analysis, where we assume the joint density of $X_{i}$ given $Z_{i}$ does not depend on the response vector $Y_{i}$. In practice, this joint density can be expressed as

$$
\begin{equation*}
P\left(X_{i}=x_{i} \mid Z_{i} ; \gamma\right)=\prod_{j=2}^{J_{i}} P\left(X_{i j}=x_{i j} \mid \bar{X}_{i j}, Z_{i} ; \gamma\right) \cdot P\left(X_{i 1}=x_{i 1} \mid Z_{i} ; \gamma\right), \tag{5}
\end{equation*}
$$

where $\bar{X}_{i j}=\left\{X_{i 1}, \ldots, X_{i, j-1}\right\}$ is the history of the covariate $X_{i j}$ until time $j-1$, and $\gamma$ is the corresponding coefficient vector.

## 3 Methods of Estimation

We denote the vector of all the parameters as $\theta=\left(\beta^{\prime}, \gamma^{\prime}, \alpha^{\prime}\right)^{\prime}$. Our main interest is in estimation of $\beta$, with $\gamma$ and $\alpha$ viewed as nuisance parameters.

### 3.1 Weighted Estimating Equation for the Response Parameters

Following the spirit of the IPWGEE approach of Robins, Rotnitzky, and Zhao (1995), we introduce a weight matrix $\Delta_{i}^{*}(\alpha)$ into the usual GEE to adjust for the effects of incomplete responses and covariates. That is, if we let $\Delta_{i}^{*}(\alpha)=\operatorname{diag}\left(I\left(R_{i j}=3\right) / \pi_{i j}, 1 \leq j \leq J_{i}\right)$, then the product $\Delta_{i}^{*}\left(Y_{i}-\mu_{i}\right)$ yields an adjusted contribution from subject $i$ which involves the observed data alone.

Moreover, this element has expectation zero, and hence unbiased estimating equations for $\beta$ can be obtained as

$$
\begin{equation*}
U^{*}(\beta, \alpha)=\sum_{i=1}^{n} U_{i}^{*}(\beta, \alpha)=0 \tag{6}
\end{equation*}
$$

where $U_{i}^{*}(\beta, \alpha)=D_{i} V_{i}^{-1} \Delta_{i}^{*}(\alpha)\left(Y_{i}-\mu_{i}\right)$ with $D_{i}=\partial \mu_{i}^{\prime} / \partial \beta$ being a $p \times J_{i}$ derivative matrix, and $V_{i}$ the working covariance matrix for the response $Y_{i}$.

In practice, the covariance matrix $V_{i}$ is often expressed as $V_{i}=F_{i}^{1 / 2} C_{i} F_{i}^{1 / 2}$, where $C_{i}$ is a working correlation matrix, and $F_{i}=\operatorname{diag}\left(v_{i j}, j=1, \ldots, J_{i}\right)$ and is assumed only depends on the marginal mean $\mu_{i}$. When the working correlation matrix $C_{i}$ is the identity matrix, (6) is computable. However, when a working independence assumption is not adopted, (6) may not be computable since elements of $D_{i} V_{i}^{-1}$ associated with the observed pairs $\left(Y_{i j}, X_{i j}\right)$ may be unknown because they involve of other missing covariates $X_{i k}(k \neq j)$. Here we modify (6) to incorporate general working correlation matrices. We define $\Delta_{i}=\left[\delta_{i j k}\right]_{J_{i} \times J_{i}}$, where $\delta_{i j k}=$ $\left[I\left(R_{i j}=1, R_{i k}=3\right)+I\left(R_{i j}=3, R_{i k}=3\right)\right] / \pi_{i j k}$ for $j \neq k, \delta_{i j j}=I\left(R_{i j}=3\right) / \pi_{i j}$, and $\pi_{i j k}=$ $P\left(R_{i j}=1, R_{i k}=3 \mid Y_{i}, X_{i}, Z_{i}\right)+P\left(R_{i j}=3, R_{i k}=3 \mid Y_{i}, X_{i}, Z_{i}\right)$. Let $M_{i}=F_{i}^{-1 / 2}\left[C_{i}^{-1} \bullet \Delta_{i}\right] F_{i}^{-1 / 2}$, where $A \bullet B=\left[a_{i j} \cdot b_{i j}\right]$ denotes the Hadamard product of $J_{i} \times J_{i}$ matrices $A=\left[a_{i j}\right]$ and $B=\left[b_{i j}\right]$. By introducing the condition that $X_{i j}$ must be observed for elements in row $j$ of $\Delta_{i}(\alpha)$, we ensure that all required elements of $D_{i}\left[V_{i}^{-1} \bullet \Delta_{i}(\alpha)\right]\left(Y_{i}-\mu_{i}\right)$ can be computed.

The generalized estimating functions for $\beta$ are given by

$$
\begin{equation*}
U(\beta, \alpha)=\sum_{i=1}^{n} U_{i}(\beta, \alpha)=0 \tag{7}
\end{equation*}
$$

where $U_{i}(\beta, \alpha)=D_{i} M_{i}\left(Y_{i}-\mu_{i}\right)$. It is easy to see that estimating function (7) depends on the observed data and the parameters only, and hence is computable.

For the estimating equations (7), to obtain a consistent estimate, the missing data model needs to be correctly specified. If the missing data model is misspecified, it can yield biased estimates. Under a missing at random mechanism, Robins, Rotnitzky, and Zhao (1994, 1995), Robins and Rotnitzky (1995), Scharfstein, Rotnitzky, and Robins (1999), and Van der Laan and Robins (2003)
proposed methods to improve the robustness of the inverse probability weighted estimates. The idea is to modify these inverse weighted equations by adding a tangent space of the conditional distribution of $R_{i}$, yielding an augmented estimating function which remains unbiased. With suitable choice of the appended function, we can get the doubly robust estimates. This approach has, to our knowledge, only been investigated to address the missingness with either incomplete response or covariate processes, but not both. Now, we describe ways for the double robustness for the general missingness patterns when either the covariates model or missing data model is correctly specified.

Following the same spirit of Van der Laan and Robins (2003), the general form of the augmented estimating functions for the general missingness patterns can be written as

$$
\begin{equation*}
\sum_{i=1}^{n}\left[U_{i}+\phi_{i}\right]=0, \tag{8}
\end{equation*}
$$

where $\phi_{i}$ is a function in the tangent space the conditional distribution of $R_{i}$ with mean zero. The optimal $\phi_{i, \text { opt }}$ is chosen as the projection of $U_{i}$ onto the tangent space of the conditional distribution of $R_{i}$. It is not hard to show that, in Hilbert space, $\phi_{i, \text { opt }}=E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}, R_{i}\right)}\left[D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right]$ with

$$
N_{i}=F_{i}^{-1 / 2}\left[C_{i}^{-1} \bullet\left(\mathbb{1}^{\prime}-\Delta_{i}\right)\right] F_{i}^{-1 / 2},
$$

where $\mathbb{1}$ is a vector a 1's with length $J_{i}$, and $Y_{i}^{m}$ and $X_{i}^{m}$ denote the missing part of $Y_{i}$ and $X_{i}$ respectively. We then can solve estimating equations

$$
S_{1}(\theta)=\sum_{i=1}^{n} S_{1 i}(\theta)=\sum_{i=1}^{n}\left\{D_{i} M_{i}\left(Y_{i}-\mu_{i}\right)+E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}, R_{i}\right)}\left[D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right]\right\}=0
$$

to obtain the estimate of $\beta$. It can be shown that the resulting estimator for $\beta$ is robust to the misspecification of either the missing data model or the covariates model. The proof if given in the Appendix.

In practice the parameters $\gamma$ and $\alpha$ are unknown, and one must replace $\gamma$ and $\alpha$ in with a consistent estimate. We describe how to obtain an estimate in the next subsection.

### 3.2 Estimation for the Nuisance Parameters

Since we are assuming the covariate is missing at random, we can obtain the estimate of $\gamma$ through maximizing likelihood estimate. Note that the likelihood for subject $i$ is $L_{i}\left(\gamma ; X_{i}, Z_{i}\right)=P\left(X_{i}=\right.$ $\left.x_{i} \mid Z_{i}\right)$. With complete data, we can solve the estimating equation $\sum_{i=1}^{n} \partial \log L_{i}\left(\gamma ; X_{i}, Z_{i}\right) / \partial \gamma^{\prime}=$ 0 to obtain the estimate $\gamma$. With incomplete data for $X_{i}$, instead, we can solve the estimating equation

$$
S_{2}(\gamma)=\sum_{i=1}^{n} S_{2 i}(\gamma)=\sum_{i=1}^{n}\left[E_{\left\{X_{i}^{m} \mid X_{i}^{o}, Z_{i}\right\}} \partial \log L_{i}\left(\gamma ; X_{i}, Z_{i}\right) / \partial \gamma^{\prime}\right]=0
$$

to obtain the consistent estimate when the distribution for $X_{i}$ is correctly specified.
For the estimation of the missing data parameter $\alpha$, we can also employ the maximum likelihood estimate. Note that the log likelihood for $\alpha$ is given by

$$
\ell(\alpha)=\sum_{i=1}^{n} \ell_{i}(\alpha)=\sum_{i=1}^{n} \sum_{j=1}^{J_{i}} \sum_{k=0}^{3} I\left(R_{i j}=k\right) \log \left(\lambda_{i j k}\right),
$$

and the score function is

$$
S_{3}(\alpha)=\sum_{i=1}^{n} S_{3 i}(\alpha)=\sum_{i=1}^{n} \sum_{j=1}^{J_{i}} \sum_{k=0}^{3} \frac{I\left(R_{i j}=k\right)}{\lambda_{i j k}} \cdot \frac{\partial \lambda_{i j k}}{\partial \alpha^{\prime}} .
$$

Solving the estimating equation $S_{3}(\alpha)=0$ leads to the maximum likelihood estimate $\hat{\alpha}$.

### 3.3 Estimation and Inferences

In the section we give details on the estimation and inference for the parameters. To obtain an estimate for $\theta$, we can solve estimating equations

$$
S(\hat{\theta})=\left[\begin{array}{c}
S_{1}(\hat{\theta})  \tag{9}\\
S_{2}(\hat{\gamma}) \\
S_{3}(\hat{\alpha})
\end{array}\right]=\sum_{i=1}^{n} S_{i}(\theta)=\sum_{i=1}^{n}\left[\begin{array}{c}
S_{1 i}(\hat{\theta}) \\
S_{2 i}(\hat{\gamma}) \\
S_{3 i}(\hat{\alpha})
\end{array}\right]=0 .
$$

It can be shown that, provided the response model $p\left(y_{i} \mid x_{i}, z_{i}\right)$ is correctly specified, either the correct specification of the missing data model $p\left(r_{i} \mid x_{i}, y_{i}, z_{i}\right)$ or the correct specification of the
covariate model $p\left(x_{i} \mid z_{i}\right)$ leads to the asymptotically unbiased estimate of $\beta$. The details of proof are given in the Appendix.

To solve estimating equations (9), we employ an EM algorithm (Dempster et al., 1977) if the covariate $X$ is discrete and Montone Carlo (MC) EM (Wei and Tanner, 1990) algorithm if the covariate $X$ is continuous. The key is that we need to calculate the conditional expectation in $S_{1}$ and $S_{2}$.

When $X$ is discrete, then the second part in $S_{1 i}$ can be written as

$$
E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}, R_{i}\right)}\left[D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right]=\sum_{\left(y_{i}^{m}, x_{i}^{m}\right)} w_{i x y}\left[D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right]
$$

where

$$
\begin{aligned}
w_{i x y} & =P\left(Y_{i}^{m}=y_{i}^{m}, X_{i}^{m}=x_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}, R_{i}\right)=P\left(Y_{i}^{m}=y_{i}^{m}, X_{i}^{m}=x_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right) \\
& =\frac{P\left(Y_{i}=y_{i}, X_{i}=x_{i} \mid Z_{i}\right)}{\sum_{\left(y_{i}^{m}, x_{i}^{m}\right)} P\left(Y_{i}=y_{i}, X_{i}=x_{i} \mid Z_{i}\right)} \\
& =\frac{P\left(Y_{i}=y_{i} \mid X_{i}=x_{i}, Z_{i}\right) P\left(X_{i}=x_{i} \mid Z_{i}\right)}{\sum_{\left(y_{i}^{m}, x_{i}^{m}\right)}\left[P\left(Y_{i}=y_{i} \mid X_{i}=x_{i}, Z_{i}\right) P\left(X_{i}=x_{i} \mid Z_{i}\right)\right]}
\end{aligned}
$$

can be regarded as a weight, where the distribution of $P\left(Y_{i}=y_{i} \mid X_{i}=x_{i}, Z_{i}\right)$ and $P\left(X_{i}=x_{i} \mid Z_{i}\right)$ can be obtained from (2) and (5), respectively.

We now introduce the EM algorithm to solve $S(\hat{\theta})=0$ as follows:

1. Obtain an initial value of the parameter $\theta=\theta^{(0)}$.
2. At the $t$ th step, we have $\theta^{(t)}$, and calculate $w_{i x y}^{(t)}=w_{i x y}\left(\theta^{(t)}\right)$ and $w_{i x}^{(t)}=w_{i x}\left(\theta^{(t)}\right)$, where

$$
w_{i x}=P\left(X_{i}^{m}=x_{i}^{m} \mid X_{i}^{o}, Z_{i}\right)=\frac{P\left(X_{i}=x_{i} \mid Z_{i}\right)}{\sum_{x_{i}^{m}} P\left(X_{i}=x_{i} \mid Z_{i}\right)} .
$$

3. Treating $w_{i x y}^{(t)}$ and $w_{i x}^{(t)}$ as fixed, solve $S\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)=0$ for $\hat{\theta}^{(t+1)}$, where

$$
S\left(\hat{\theta}^{(t+1)} \mid \hat{\left.\theta^{(t)}\right)}\right)=\left[\begin{array}{c}
S_{1}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)  \tag{10}\\
S_{2}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right) \\
S_{3}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)
\end{array}\right]=\sum_{i=1}^{n}\left[\begin{array}{c}
S_{1 i}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right) \\
S_{2 i}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right) \\
S_{3 i}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)
\end{array}\right],
$$

$$
S_{1 i}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)=D_{i} M_{i}\left(\hat{\theta}^{(t)}\right)\left(Y_{i}-\mu_{i}\right)+\sum_{\left(y_{i}^{m}, x_{i}^{m}\right)} w_{i x y}^{(t)}\left[D_{i} N_{i}\left(\hat{\theta}^{(t)}\right)\left(Y_{i}-\mu_{i}\right)\right],
$$

and

$$
S_{2 i}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)=\sum_{x_{i}^{m}} w_{i x}^{(t)} \partial \log L_{i}\left(\gamma ; x_{i}, z_{i}\right) / \partial \gamma^{\prime}
$$

4. Iterate until convergence to, say $\hat{\theta}$, which gives the solution to $S(\hat{\theta})=0$.

When $X$ is continuous, we employ the MCEM algorithm. Specifically, we solve (10) with

$$
S_{1 i}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)=D_{i} M_{i}\left(\hat{\theta}^{(t)}\right)\left(Y_{i}-\mu_{i}\right)+\int_{\left(y_{i}^{m}, x_{i}^{m}\right)} w_{i x y}^{(t)}\left[D_{i} N_{i}\left(\hat{\theta}^{(t)}\right)\left(Y_{i}-\mu_{i}\right)\right] d Y_{i}^{m} d X_{i}^{m}
$$

and

$$
S_{2 i}\left(\hat{\theta}^{(t+1)} \mid \hat{\theta}^{(t)}\right)=\int_{x_{i}^{m}} w_{i x}^{(t)} \partial \log L_{i}\left(\gamma ; x_{i}, z_{i}\right) / \partial \gamma^{\prime} d X_{i}^{m}
$$

where the weights become

$$
\begin{aligned}
w_{i x y}^{(t)} & =P\left(Y_{i}^{m}=y_{i}^{m}, X_{i}^{m}=x_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i} ; \theta^{(t)}\right) \\
& =\frac{P\left(Y_{i}=y_{i}, X_{i}=x_{i} \mid Z_{i} ; \theta^{(t)}\right)}{\int_{\left(y_{i}^{m}, x_{i}^{m}\right)} P\left(Y_{i}=y_{i}, X_{i}=x_{i} \mid Z_{i} ; \theta^{(t)}\right) d Y_{i}^{m} d X_{i}^{m}} \\
& =\frac{P\left(Y_{i}=y_{i} \mid X_{i}=x_{i}, Z_{i} ; \theta^{(t)}\right) P\left(X_{i}=x_{i} \mid Z_{i} ; \theta^{(t)}\right)}{\int_{\left(y_{i}^{m}, x_{i}^{m}\right)} P\left(Y_{i}=y_{i} \mid X_{i}=x_{i}, Z_{i} ; \theta^{(t)}\right) P\left(X_{i}=x_{i} \mid Z_{i} ; \theta^{(t)}\right) d Y_{i}^{m} d X_{i}^{m}}
\end{aligned}
$$

and

$$
w_{i x}^{(t)}=P\left(X_{i}^{m}=x_{i}^{m} \mid X_{i}^{o}, Z_{i} ; \theta^{(t)}\right)=\frac{P\left(X_{i}=x_{i} \mid Z_{i} ; \theta^{(t)}\right)}{\int_{x_{i}^{m}} P\left(X_{i}=x_{i} \mid Z_{i} ; \theta^{(t)}\right) d X_{i}^{m}} .
$$

To solve (10) that equals 0 , we need the integrations. In this case, rather than use numerical integration, we may employ a Monte Carlo method. To be specific, we sample $\left(y_{i}^{m}, x_{i}^{m}\right)$ from the conditional density $w_{i x y}^{(t)}$ using the adaptive rejection algorithm of Gilks \& Wild (1992). Repeat this $L$ times, with the $l$ th draw of $\left(y_{i}^{m}, x_{i}^{m}\right)$ denoted by $\left(y_{i}^{m l(t)}, x_{i}^{m l(t)}\right)$. Then

$$
\begin{aligned}
& \int_{\left(y_{i}^{m}, x_{i}^{m}\right)} w_{i x y}^{(t)}\left[D_{i} N_{i}\left(\hat{\theta}^{(t)}\right)\left(Y_{i}-\mu_{i}\right)\right] d Y_{i}^{m} d X_{i}^{m} \\
= & \left.\frac{1}{L} \sum_{l=1}^{L}\left[D_{i} N_{i}\left(\hat{\theta}^{(t)}\right)\left(Y_{i}-\mu_{i}\right)\right]\right|_{\left(Y_{i}^{m}, X_{i}^{m}\right)=\left(y_{i}^{m l(t)}, x_{i}^{m l(t)}\right)^{\prime}},
\end{aligned}
$$

and

$$
\int_{x_{i}^{m}} w_{i x}^{(t)} \partial \log L_{i}\left(\gamma ; x_{i}, z_{i}\right) / \partial \gamma^{\prime} d X_{i}^{m}=\frac{1}{L} \sum_{l=1}^{L} \partial \log L_{i}\left(\gamma ; x_{i}, z_{i}\right) /\left.\partial \gamma^{\prime}\right|_{X_{i}^{m}=x_{i}^{m l(t)}}
$$

To state the asymptotic properties of $\hat{\beta}$, we define

$$
\begin{aligned}
& \Gamma(\beta, \gamma, \alpha)=E\left[\partial S_{1 i}(\beta, \gamma, \alpha) / \partial \beta\right], \\
& I_{12}(\beta, \gamma, \alpha)=E\left[\partial S_{1 i}(\beta, \gamma, \alpha) / \partial \gamma\right], \\
& I_{13}(\beta, \gamma, \alpha)=E\left[\partial S_{1 i}(\beta, \gamma, \alpha) / \partial \alpha\right], \\
& I_{2}(\gamma)=E\left[\partial S_{2 i}(\gamma) / \partial \gamma\right], \\
& I_{3}(\gamma)=E\left[\partial S_{3 i}(\gamma) / \partial \alpha\right], \\
& Q_{i}(\beta, \gamma, \alpha)=S_{1 i}(\beta, \gamma, \alpha)-I_{12}(\beta, \gamma, \alpha) I_{2}^{-1}(\gamma) S_{2 i}(\gamma)-I_{13}(\beta, \gamma, \alpha) I_{3}^{-1}(\alpha) S_{3 i}(\alpha) .
\end{aligned}
$$

Theorem 1. Suppose that the regularity conditions state in the Appendix hold, if either the missing data model or the covariate model is correctly specified, we have

$$
n^{1 / 2}\left(\hat{\beta}-\beta_{0}\right) \rightarrow N\left(0, \Gamma^{-1}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) \Sigma\left[\Gamma^{-1}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right)\right]^{\prime}\right)
$$

where $\beta_{0}$ is the true value of $\beta, \gamma_{0}$ and $\alpha_{0}$ are the probability limits of $\hat{\gamma}$ and $\hat{\alpha}$, and $\Sigma=$ $E\left[Q_{i}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) Q_{i}^{\prime}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right)\right]$.

The proof is given in the Appendix. To make inferences, the matrix $\Gamma$ can be consistently estimated with

$$
\hat{\Gamma}=n^{-1} \sum_{i=1}^{n}\left[\partial S_{1 i}(\hat{\theta} \mid \hat{\theta}) / \partial \beta\right],
$$

and $\Sigma$ can be consistently estimated with $\hat{\Sigma}=n^{-1} \sum_{i=1}^{n}\left[\hat{Q}_{i} \hat{Q}_{i}^{\prime}\right]$, where

$$
\begin{gathered}
\hat{Q}_{i}=S_{1 i}(\hat{\theta} \mid \hat{\theta})-\hat{I}_{12}(\hat{\theta} \mid \hat{\theta}) \hat{I}_{2}^{-1}(\hat{\theta} \mid \hat{\theta}) S_{2 i}(\hat{\theta} \mid \hat{\theta})-\hat{I}_{13}(\hat{\theta} \mid \hat{\theta}) \hat{I}_{3}^{-1}(\hat{\alpha}) S_{3 i}(\hat{\alpha}), \\
\hat{I}_{12}(\hat{\theta} \mid \hat{\theta})=n^{-1} \sum_{i=1}^{n}\left[\partial S_{1 i}(\hat{\theta} \mid \hat{\theta}) / \partial \gamma\right],
\end{gathered}
$$

$$
\begin{aligned}
\hat{I}_{13}(\hat{\theta} \mid \hat{\theta}) & =n^{-1} \sum_{i=1}^{n}\left[\partial S_{1 i}(\hat{\theta} \mid \hat{\theta}) / \partial \alpha\right], \\
\hat{I}_{2}(\hat{\theta} \mid \hat{\theta}) & =n^{-1} \sum_{i=1}^{n}\left[\partial S_{2 i}(\hat{\theta} \mid \hat{\theta}) / \partial \gamma\right], \\
\hat{I}_{3}(\hat{\alpha}) & =n^{-1} \sum_{i=1}^{n}\left[\partial S_{3 i}(\hat{\alpha}) / \partial \alpha\right] .
\end{aligned}
$$

## 4 Numerical Studies

### 4.1 Performance of the Proposed Estimates

In this subsection, we evaluate the performance of the proposed method compared to other methods commonly used in practice through simulation studies. In the simulation studies, we focus on a setting where $J_{i}=J=3$ and $n=500$. We simulate the longitudinal binary responses from a model with

$$
\begin{equation*}
\operatorname{logit} \mu_{i j}=\beta_{0}+\beta_{1} X_{i j}+\beta_{2} Z_{i j} \tag{11}
\end{equation*}
$$

where $Z_{i j}$ is a time variant covariate generated from $\operatorname{Bin}(1,0.5)$, and $X_{i j}$ is a time variant binary covariate which may be missing at some time points and is generated from the model

$$
\begin{equation*}
\operatorname{logit} \omega_{i j}=\gamma_{0}+\gamma_{1} X_{i, j-1}+\gamma_{2} Z_{i j}, \tag{12}
\end{equation*}
$$

where $\omega_{i j}=P\left(X_{i j}=1 \mid \bar{X}_{i j}, Z_{i j}\right)$. We take $\beta_{0}=\log (1.5), \beta_{1}=\log (0.5), \beta_{2}=\log (2), \gamma_{0}=$ $\log (1), \gamma_{2}=2$, and $\gamma_{1}$ varies from -2 to 2 . The correlation matrix is exchangeable with correlation coefficient $\rho$.

For the missing data process, we take

$$
\begin{align*}
\log \left(\frac{\lambda_{i j k}}{\lambda_{i j 0}}\right)= & \alpha_{0 k}+\alpha_{1 k 1} I\left(R_{i, j-1}=1\right)+\alpha_{1 k 2} I\left(R_{i, j-1}=2\right)+\alpha_{1 k 3} I\left(R_{i, j-1}=3\right) \\
& +\alpha_{2 k} y_{i, j-1}^{o}+\alpha_{3 k} x_{i, j-1}^{o}, \tag{13}
\end{align*}
$$

for $k=1,2,3$, where $y_{i, j-1}^{o}=y_{i, j-1}$ if $y_{i, j-1}$ is observed and 0 otherwise, $x_{i, j-1}^{o}=x_{i, j-1}$ if $x_{i, j-1}$ is observed and 0 otherwise. The true values are taken as $\alpha_{0 k}=\log (1.5), \alpha_{1 k 1}=\log (1.5)$, $\alpha_{1 k 2}=\log (1.3), \alpha_{1 k 3}=\log (1.1), \alpha_{3 k}=-2$, and $\alpha_{2 k}=\alpha_{2}$ varies from -2 to 2 .

In the simulations, we always assume the model for $\left(y_{i} \mid x_{i}, z_{i}\right)$ is correctly specified. We consider the following seven methods: 1) both the missing data model and covariate model are correctly specified, which we denote $(x+, r+)$; 2) the missing data model is correctly specified, but the model for $\omega$ is misspecified as

$$
\begin{equation*}
\operatorname{logit} \omega_{i j}=\gamma_{0}^{*}+\gamma_{2}^{*} Z_{i j} \tag{14}
\end{equation*}
$$

which we denote $(x-, r+) ; 3)$ the model for $\omega$ is correctly specified, but the missing data model is misspecified as

$$
\begin{align*}
\log \left(\frac{\lambda_{i j k}}{\lambda_{i j 0}}\right)= & \alpha_{0 k}^{*}+\alpha_{1 k 1}^{*} I\left(R_{i, j-1}=1\right)+\alpha_{1 k 2}^{*} I\left(R_{i, j-1}=2\right)+\alpha_{1 k 3}^{*} I\left(R_{i, j-1}=3\right) \\
& +\alpha_{3 k}^{*} x_{i, j-1}^{o} \tag{15}
\end{align*}
$$

which we denote $(x+, r-)$; and 4) both the model for $\omega$ is misspecified as (14), and the missing data model is misspecified as (15), which we denote $(x-, r-)$; 5) the EM algorithm with the covariate model incorrectly specified as (14), which we denote $\operatorname{EM}(x-) ; 6)$ the simple weighted GEE (not the robust method) method that with the missing data model incorrectly specified as (15), which we denote $\operatorname{GEE}(r-)$; 7) the complete case analysis using maximum likelihood method, which we denote cc. In each setting, we perform 2000 simulations.

The results are reported in Tables 1 to 3 , where the bias is the percent relative bias, SD is the standard deviation for the 2000 simulations, and CP represents the empirical coverage probability for $95 \%$ confidence intervals. It is seen that the $(x-, r-), \operatorname{EM}(x-), G E E(r-)$ and complete case approaches yield larger biases and poor coverage probabilities; as the response association $\rho$ increases, the performance decreases. The $(x+, r+),(x+, r-)$ and $(x-, r+)$ methods provide ignorable finite sample biases, and gives good coverage probabilities; $(x-, r+)$ estimate is more
efficient than $(x+, r-)$ estimate, indicating that the efficiency of the estimate is more sensitive to the misspefication of the missing data model than to the covariate model.

### 4.2 Impact of Model Misspecification

The validity of this algorithm depends on correct specification of the model for the response process and either the observation process and the missing covariate process. Here we investigate the impact of misspecification of the observation process model and/or the missing covariate process.

Let $\hat{\theta}^{\dagger}$ denote the estimator for $\theta$ when the missing data process and the covariate process are misspecified. To characterize the asymptotic bias of $\hat{\theta}^{\dagger}$, we use the methods of White (1982) to find the value to which $\hat{\theta}^{\dagger}$ converges. In the spirit of Rotnitzky and Wypij (1994), Fitzmaurice, Molenberghs, and Lipsitz (1995) and Cook, Zeng, and Yi (2004), we take the expectation of $S_{i}(\theta)$ with respect to the true distribution of $G=\left(R_{i}, Y_{i}, X_{i}, Z_{i}\right)$ and set it equal to zero. The solution to this equation, denoted $\theta^{\dagger}$, is the value to which $\hat{\theta}^{\dagger}$ converges in probability. If $\mathcal{G}$ is the sample space for $G$, and $P(g ; \theta)$ is the true probability of observing the realized value $g$ of $G$, then solving the equation

$$
\begin{equation*}
\sum_{g \in \mathcal{G}} S_{i}\left(\theta^{\dagger}\right) \cdot P(g ; \theta)=0 \tag{16}
\end{equation*}
$$

gives the relationship between $\theta$ and $\theta^{\dagger}$, and enables one to characterize the asymptotic bias.
In this study, response measurements are featured by the same model (11) with $\rho=0.3$; the true model for missing data indicators is (13), and the true model for the missing covariate model is (12).

Now we consider the misspecification the missing data model and the covariate model. Figures 1 and 2 plot the asymptotic percent relative biases of $\beta_{1}$ and $\beta_{2}$ against $\gamma_{1}$ as $\alpha_{2}$ changes. It is seen that $\beta_{1}$ and $\beta_{2}$ are sensitive to the misspecification of the missing data and covariate models. As the absolute value of $\alpha_{2}$ goes to 0 , the relative biases decrease; as the absolute value of $\gamma_{1}$ goes to 0 , the relative biases decrease. For fixed $\alpha_{2}$ that are not very big, the relative biases lines are more flat, and the biases are small, indicating that the estimate is less sensitive to the misspecification of

Table 1: Empirical bias, standard deviation and coverage probabilities for seven approaches to estimation and inference with incomplete covariate and response data ( $\rho=0.6$ )

| $\gamma_{1}$ | $\alpha_{2}$ | Method | $\beta_{0}$ |  |  | $\beta_{1}$ |  |  | $\beta_{2}$ |  |  |

the covariate model; while for fixed $\gamma_{1}$ that are not very close to 0 , the relative biases change big as $\alpha_{2}$ changes, indicating that the estimate is more sensitive to the misspecification of the missing data model.

Figure 1: Asymptotic percent relative bias of $\beta_{1}$ with misspecified covariate model and missing data model

In summary, estimation of the response parameters is generally sensitive to misspecification of the missing data model and covariate model, although the degree of the sensitivity could be varying for different kinds of misspecification. Our asymptotic studies also suggest that if the missing data model is modeled approximately correct, then there is very good chance that the proposed method will reduce the bias with the covariate model is misspecified.

Figure 2: Asymptotic percent relative bias of $\beta_{2}$ with misspecified covariate model and missing data model

## 5 Application to an Alzheimer's Disease Study

We apply the proposed method to the National Alzheimer's Coordinating Center (NACC) Uniform Data Set (UDS). One of the goal of the study is to investigate the risk factors that influence the onset of dementia. The response is the diagnostic of dementia (Yes/No). The covariates that may influence the status of dementia include sex, congestive heart failure (CVCHF, yes/no), family history of dementia (FHDEM, yes/no), diabetes (yes/no), behavioral assessment (depression or dysphoria, yes/no), hypertension (yes/no), education (years), Mini-Mental State Exam (MMSE) score, and age. There are 16223 subjects from 29 Alzheimer's Disease Centers included at the entry of this study. Follow-up visits for subjects are scheduled at approximately one-year intervals, with up to four clinical visits at present. Due to some reasons, there are some missing data for the response and the behavioral assessment covariate. There are 8724 subjects with complete data observed. About $11.9 \%$ subjects miss both the response and behavioral assessment; about $31.2 \%$ subjects miss the response but observe behavioral assessment; about $3.2 \%$ subjects miss the behavioral assessment but observe the response; and about $53.7 \%$ subjects observe both the response and the behavioral assessment covariate.

Consider the regression model for the response process

$$
\operatorname{logit} \mu_{i j}=u_{i j}^{\prime} \beta
$$

where $u_{i j}$ is the covariate vector at time point $j$, which include the function of sex, CVCHF, FHDEM, diabetes, depression, hypertension, education, MMSE, and age.

For the missing indicators, we build regression models

$$
\log \left(\frac{\lambda_{i j k}}{\lambda_{i j 0}}\right)=v_{i j k}^{\prime} \alpha_{k}, \quad k=1,2,3,
$$

where $v_{i j k}$ include function of history of the missing indicators, sex, CVCHF, FHDEM, diabetes, depression, hypertension, education, MMSE, and age.

For the covariate, we build model

$$
\operatorname{logit} \omega_{i j}=w_{i j}^{\prime} \gamma, \quad j>1,
$$

where $\omega_{i j}$ is the conditional probability that patient $i$ at time $j$ is depressed given the covariate vector $w_{i j}$ which may include function of history of the covariate, sex, CVCHF, FHDEM, diabetes, depression, hypertension, education, MMSE, and age.

In line with the simulation study, here we use three methods to analyze the data. The first method, labeled "EM", is the EM algorithm; the second method, labeled "WEE", is the doubly robust method; the third method is the complete case analysis; the results are reported in Table 4. The complete case (CC) method reveal that sex has no significant effect on the dementia, but the EM and the WEE methods reveal that it is significant; all the three methods reveal that CVCHF has no significant impact on the dementia, depression has a negative effect on the onset of dementia, MMSE has a positive effect to protect the onset of dementia, diabetes and hypertension have positive effects to protect the onset of dementia; for the family history of dementia, the CC analysis indicates that it has no significant effect, but the EM and WEE method analyses indicate that it has a negative effect on the onset of dementia; for the education level, the EM and WEE methods reveal that it has no significant effect on the onset of dementia, but the CC analysis reveals that it is not significant; for age, all three methods indicate that it has a negative effect on the onset of dementia.

For the missing data model, we carry out standard diagnostic tests for the fit of regression models by comparing a model with an expanded model to do a model selection. Here, we only list the results for the final model without reporting the tables due to the limiting space. Significance of the previous missing indicator indicates that there exists strong series dependence; sex, CVDHF, DEPD, MMSE, FHDEM, diabetes, hypertension, education, age and the observed previous response are also significant in some missing data models, indicating that data are not missing completely at random.

## 6 Discussion

The consistent estimates of longitudinal data with both missing response and missing covariates under missing at random depend on the correct specification of the missing data model or the covariate model. Likelihood-based method is robust to the misspecification of the missing data process model, while the weighted estimating equation method is robust to the misspecification of the covariate model. In this paper we develop a doubly robust estimate method, which is robust to the misspeficiation of the missing data model or the misspecification of the covariate model, but not both. Simulation studies have shown that, subject to the correct specification of the response model, the estimators are consistent and empirical studies have shown that there is negligible bias in finite samples, when the missing data model is correctly specified or the covariate model is correctly specified.

The asymptotic studies have provided insight into the nature of the biases one can expect with
different types of model misspecification, which suggests that there is a very good chance that our proposed method will reduce the bias with the covariate model is misspecified and the missing data model is approximately correct. Use of model diagnostics for the missing data process, perhaps most easily carried out in the MAR setting through model expansion, is warranted. It appears that empirically there is often little price to pay for introducing additional covariates into the missing data regression models. This is comforting since the more comprehensive the missing data model the more plausible it is that there is no residual dependence on the missing response, say. To provide a final check against the effects of data MNAR, sensitivity analyses can be carried out as described by Rotnitzky et al. (1998) and Scharfstein et al. (1999). It is generally not possible to check formally for the presence of a MNAR mechanism, so sensitivity analysis are required if this is a serious concern.

We focussed here primarily on estimation and inference regarding one covariate is subject to missing. Multiple covariates subject to missing are very common in practice. A future research is to extend this method to the multiple missing covariates problem. The idea is that we build missing data models to construct the weights in the weighted estimating equations, and we also need to build joint models for the covariates that are subject to missing, which is challenge in practice, especially for missing covariates with both continuous and categorical.

## Appendix: Proof of the Doubly Robust Estimation Property and Theorem 1

## Proof of the doubly robust estimation property.

Using the first Taylor series expansion, it can be shown that

$$
n^{1 / 2}(\hat{\theta}-\theta) \approx n\left\{-\frac{\partial E[S(\theta)]}{\partial \theta}\right\}^{-1} n^{-1 / 2} S(\theta)
$$

which implies that

$$
\begin{equation*}
n^{1 / 2}(\hat{\beta}-\beta) \approx n I^{11} n^{-1 / 2} S_{1}(\theta)+n I^{12} n^{-1 / 2} S_{2}(\theta)+n I^{13} n^{-1 / 2} S_{3}(\alpha), \tag{17}
\end{equation*}
$$

where $I^{11}, I^{12}$, and $I^{13}$ are the appropriate submatrices of $\{-\partial E[S(\theta)] / \partial \theta\}^{-1}$.

1. Missing data model is correctly specified

Suppose missing data model and $p\left(y_{i} \mid x_{i}, z_{i}\right)$ are correctly specified, but the distribution of $\left(x_{i} \mid z_{i}\right)$ is not correctly specified. Then, in (9) we rewrite $E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}, R_{i}\right)}[\cdot]$ and $E_{\left(X_{i}^{m} \mid X_{i}^{o}, Z_{i}, R_{i}\right)}[\cdot]$ as $E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right)}^{*}[\cdot]$ and $E_{\left(X_{i}^{m} \mid X_{i}^{o}, Z_{i}\right)}^{*}[\cdot]$ because of the MAR assumption, where the subscript "**" represents the expectation taken over the wrongly specified distribution for $\left(y_{i}, x_{i} \mid z_{i}\right)$ and $\left(x_{i} \mid z_{i}\right)$.

If the missing data model is correctly specified, we have $E\left[\delta_{i j k}\right]=1$, and thus $E\left[\Delta_{i}\right]=\mathbb{1} \mathbb{1}^{\prime}$, $E\left[M_{i}\right]=V_{i}^{-1}$, and $E\left[N_{i}\right]=0$. So, we have $E\left[D_{i} M_{i}\left(Y_{i}-\mu_{i}\right)\right]=E\left[D_{i} V_{i}^{-1}\left(Y_{i}-\mu_{i}\right)\right]=0$, and $E\left\{E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}, R_{i}\right)}^{*}\left[D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right]\right\}=E\left\{E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right)}^{*}\left[D_{i} \cdot 0 \cdot\left(Y_{i}-\mu_{i}\right)\right]\right\}=0$, if the distribution of $\left(y_{i} \mid x_{i}, z_{i}\right)$ is correctly specified. That means $E\left[S_{1}(\theta)\right]=0$. It is easy to show that $E\left[S_{3}(\alpha)\right]=0$.

Now if the distribution of $\left(x_{i} \mid z_{i}\right)$ is incorrectly specified, then $E\left[S_{2}(\theta)\right] \neq 0$. However, the second term on the right hand side of (17) still has expectation equal to 0 . Using the theory of partitioned matrices, it can be shown that $I^{12}=0$ if $E\left[\partial S_{1}(\theta) / \partial \gamma\right]=0$. Note that the first term of $S_{1}(\theta)$ does not depend on $\gamma$, so the derivative is equal to 0 , hence

$$
\begin{aligned}
E\left\{\frac{\partial S_{1 i}(\theta)}{\partial \gamma}\right\} & \left.=E\left\{\frac{\partial E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right)}^{*} E_{\left(R_{i} \mid Y_{i}, X_{i}, Z_{i}\right)}}{\partial \gamma}\right\} D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right] \\
& =E\left\{\frac{\partial E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right)}^{*}[0]}{\partial \gamma}\right\} \\
& =0
\end{aligned}
$$

Thus all the terms on the right hand side of (17) have expectation equal to 0 , and $\hat{\beta}$ is asymptotically unbiased.
2. $p\left(x_{i} \mid z_{i}\right)$ correctly specified.

Suppose that the distribution of $\left(y_{i} \mid x_{i}, z_{i}\right)$ and $\left(x_{i} \mid z_{i}\right)$ are correctly specified but the missing data model is incorrectly specified. To be specific, suppose that $\pi_{i j k}$ is misspecified as $\pi_{i j k}^{*}$,
and $\pi_{i j}^{x}$ is misspecified as $\pi_{i j}^{x *}$, which are still functions of $x_{i}, y_{i}$ and $z_{i}$. We define $\tilde{\Delta}_{i}=\left[\tilde{\delta}_{i j k}\right]$ with $\tilde{\delta}_{i j k}=\left[P\left(R_{i j}=1, R_{i k}=3 \mid Y_{i}, X_{i}, Z_{i}\right)+P\left(R_{i j}=3, R_{i k}=3 \mid Y_{i}, X_{i}, Z_{i}\right)\right] / \pi_{i j k}^{*}$ for $k \neq j$ and $\tilde{\delta}_{i j j}=P\left(R_{i j}=3 \mid Y_{i}, X_{i}, Z_{i}\right) / \pi_{i j}^{*}$, and

$$
\tilde{\Delta}_{i}^{*}=\operatorname{diag}\left(P\left(R_{i j}=2 \text { or } 3 \mid X_{i}, Y_{i}, Z_{i}\right) / \pi_{i j}^{x *}, j=1, \ldots, J\right) .
$$

We show that $E\left[S_{1}(\theta)\right]=0, E\left[S_{2}(\theta)\right]=0$ and $I^{13}=0$, implying that each term on the right hand side of (17) has 0 expectation and $\hat{\beta}$ is asymptotically unbiased.

Note that expectation of the first term of $S_{1 i}(\theta)$ is

$$
E\left[D_{i} M_{i}\left(Y_{i}-\mu_{i}\right)\right]=E\left[D_{i} F_{i}^{-1 / 2}\left[C_{i} \bullet \tilde{\Delta}_{i}\right] F_{i}^{-1 / 2}\left(y_{i}-\mu_{i}\right)\right] .
$$

If both $p\left(y_{i} \mid x_{i}, z_{i}\right)$ and $p\left(x_{i} \mid z_{i}\right)$ are correctly specified, then the joint probability $p\left(y_{i}, x_{i} \mid z_{i}\right)$ is correctly specified, and hence the expectation of the second term of $S_{1 i}(\theta)$ is

$$
\begin{aligned}
& E\left\{E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}, R_{i}\right)}\left[D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right]\right\} \\
= & E\left\{E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right)}\left[D_{i} F_{i}^{-1 / 2}\left[C_{i} \bullet\left(\mathbb{1} \mathbb{1}^{\prime}-\tilde{\Delta}_{i}\right)\right] F_{i}^{-1 / 2}\left(Y_{i}-\mu_{i}\right)\right]\right\} .
\end{aligned}
$$

Thus we have

$$
\begin{aligned}
E\left[S_{1}(\theta)\right] & =E\left[D_{i} M_{i}\left(Y_{i}-\mu_{i}\right)\right]+E\left[D_{i} N_{i}\left(Y_{i}-\mu_{i}\right)\right] \\
& =E\left[D_{i} F_{i}^{-1 / 2} C_{i}^{-1} F_{i}^{-1 / 2}\left(Y_{i}-\mu_{i}\right)\right] \\
& =E\left[D_{i} V_{i}^{-1}\left(Y_{i}-\mu_{i}\right)\right] \\
& =0
\end{aligned}
$$

if the distribution of $\left(y_{i} \mid x_{i}, z_{i}\right)$ is correctly specified. Similarly, we can prove that $E\left[S_{2 i}(\theta)\right]=$ 0.

If the missing data model is misspecified, then $E\left[S_{3}(\alpha)\right] \neq 0$. However, the third term on the right hand side of (17) still has expectation 0 if $I^{13}=0$. By using the theory of partitioned
matrices, we can show that $I^{13}=0$ if $E\left[\partial S_{1}(\theta) / \partial \alpha\right]=0$. Note that

$$
\begin{aligned}
& E\left\{\frac{\partial S_{1 i}(\theta)}{\partial \alpha_{j}}\right\} \\
= & E\left\{D_{i} F_{i}^{-1 / 2}\left[C_{i}^{-1} \bullet \frac{\partial \Delta_{i}}{\partial \alpha_{j}}\right] F_{i}^{-1 / 2}\left(Y_{i}-\mu_{i}\right)\right\} \\
& +E\left\{E_{\left(Y_{i}^{m}, X_{i}^{m} \mid Y_{i}^{o}, X_{i}^{o}, Z_{i}\right)}\left[F_{i}^{-1 / 2}\left[C_{i}^{-1} \bullet\left(-\frac{\partial \Delta_{i}}{\partial \alpha_{j}}\right)\right] F_{i}^{-1 / 2}\left(Y_{i}-\mu_{i}\right)\right]\right\} \\
= & 0
\end{aligned}
$$

for $j=1, \ldots, p_{3}$, where $p_{3}=\operatorname{dim}(\alpha)$. Then all the three terms on the right hand side of (17) have expectation 0 , and $\hat{\beta}$ is asymptotically unbiased if the distribution of $\left(y_{i} \mid x_{i}, z_{i}\right)$ and $\left(x_{i} \mid z_{i}\right)$ are correctly specified.

## Proof of Theorem 1.

The regularity conditions required in Theorem 1 include standard conditions that are assumed for the estimating function theory, plus the requirement for the missing data processes and covariate process. Specifically, we require $P\left(R_{i j}=3 \mid \bar{R}_{i j}, Y_{i}, X_{i}, Z_{i}\right)$ is bounded away from zero. This condition ensures that the estimating functions in (7) are bounded, which is necessary for a $\sqrt{n}$ consistent estimator. Other routine conditions are similar to those in Robins, Rotnitzky, and Zhao (1995) with a proper modification.

By standard Taylor expansion arguments we have that

$$
\begin{equation*}
n^{1 / 2}\left(\hat{\gamma}-\gamma_{0}\right)=-I_{2}^{-1}\left(\gamma_{0}\right) n^{-1 / 2} \sum_{i=1}^{n} S_{2 i}\left(\gamma_{0}\right)+o_{p}(1) \tag{18}
\end{equation*}
$$

and

$$
\begin{equation*}
n^{1 / 2}\left(\hat{\alpha}-\alpha_{0}\right)=-I_{3}^{-1}\left(\alpha_{0}\right) n^{-1 / 2} \sum_{i=1}^{n} S_{3 i}\left(\alpha_{0}\right)+o_{p}(1) . \tag{19}
\end{equation*}
$$

Furthermore, based on the proof of the doubly robust properties, we have $E\left[S_{1 i}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right)\right]=0$ if either the missing data model or the covariate model is correctly specified. Thus, another Taylor
expansion gives

$$
\begin{align*}
0= & n^{-1 / 2} \sum_{i=1}^{n} S_{1 i}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right)+\Gamma\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) n^{1 / 2}\left(\hat{\beta}-\beta_{0}\right)+I_{12}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) n^{1 / 2}\left(\hat{\gamma}-\gamma_{0}\right) \\
& +I_{13}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) n^{1 / 2}\left(\hat{\alpha}-\alpha_{0}\right)+o_{p}(1) \tag{20}
\end{align*}
$$

Replacing (18) and (19) into (20), we obtain

$$
\begin{aligned}
0= & n^{-1 / 2} \sum_{i=1}^{n} S_{1 i}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right)+\Gamma\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) n^{1 / 2}\left(\hat{\beta}-\beta_{0}\right) \\
& -I_{12}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) I_{2}^{-1}\left(\gamma_{0}\right) n^{-1 / 2} \sum_{i=1}^{n} S_{2 i}\left(\gamma_{0}\right) \\
& -I_{13}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) I_{3}^{-1}\left(\alpha_{0}\right) n^{-1 / 2} \sum_{i=1}^{n} S_{3 i}\left(\alpha_{0}\right)+o_{p}(1)
\end{aligned}
$$

If $\Gamma\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right)$ is nonsingular, we have

$$
n^{1 / 2}\left(\hat{\beta}-\beta_{0}\right)=-\Gamma^{-1}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right) n^{-1 / 2} \sum_{i=1}^{n} Q_{i}\left(\beta_{0}, \gamma_{0}, \alpha_{0}\right)+o_{p}(1)
$$

Then the asymptotic distribution of $n^{1 / 2}\left(\hat{\beta}-\beta_{0}\right)$ follows by the Slutsky's theorem and the central limit theorem.
